PLATE  
(Bound at the back of this appendix)

Plate No.

- 1      Location of Surface Water Quality Monitoring  
Program Stations, 1964-65.

#### ACKNOWLEDGMENTS

The extensive coverage of the surface water quality monitoring program in Southern California has been made possible through the cooperation of federal, state, and local agencies. The Department wishes to acknowledge the valuable assistance and cooperation received from the agencies listed below.

United States Geological Survey

California Department of Public Health,  
Division of Laboratories.

The Metropolitan Water District of Southern California

Los Angeles County Health Department

Imperial County Health Department

City of Long Beach Health Department

City of Los Angeles Department of Water and Power

Fruit Growers Laboratory, Santa Paula

ABSTRACT

Appendix D to Volume V, Bulletin No. 130-65, contains data on the chemical (including trace elements and synthetic detergents), physical, radiological, and bacteriological characteristics of surface waters in Southern California for the 1964-65 water year. A foldout plate shows the locations of the 52 surface water sampling stations.

## INTRODUCTION

Appendix D to Volume V of Bulletin No. 130-65 contains data on the chemical (including trace elements and synthetic detergents), physical, radiological, and bacteriological characteristics of the surface waters in the Southern California area (see Figure 1) for the 1964-65 water year. Samples were collected at 52 stations whose locations are shown on Plate 1. The stations are listed in Table D-1.

## MEASUREMENT TECHNIQUES

Effective use of surface water quality data depends on the accuracy and availability of the data. To insure their accuracy, certain methods and procedures have been established. Coding systems have been developed to make the data readily available and usable when needed.

Discussion of the measurement techniques followed in the program include definitions of the terms used, field and laboratory procedures, reporting methods, accuracy of the reported results, the significant numbers retained, and limitations of the data.

### Definitions

The following definitions will assist the reader in understanding the terms used in this appendix.

Water Year is the 12-month period from October 1 of any year through September 30 of the following year, and is designated by the calendar year in which it ends.

Cubic feet per second (cfs) is the unit rate of discharge of water.

It is the number of cubic feet of water passing a given point in one second.

Standard Methods are the methods of analysis for substances in water adopted jointly by the American Public Health Association, American Water Works Association, and Water Pollution Control Federation. They represent the best current analytic procedures and are published as "Standard Methods for the Examination of Water and Waste Water". The current publication is the 12th edition, dated 1965.

#### Methods and Procedures

Because of the possible effect that season, time, and method of sampling may have on the analyses obtained, an explanation of the procedures established for surface water sample collection and their analyses and reporting is given below.

#### Field Procedures

For complete mineral and bacteriological analyses, water samples were collected monthly in the northern portion of the Southern California area, and bimonthly in the southern portion. The Colorado River stations above Yuma, Arizona, however, were sampled only twice a year. In addition, samples were collected at most stations for radiological analyses and at selected stations for trace element analyses in May and September. The samples collected for bacteriological examination were transported on ice to the laboratories as quickly as possible.

At the time surface samples were collected for laboratory examination, field determinations were made for water temperature, hydrogen ion concentration (pH), and for dissolved oxygen concentration by the modified Winkler method. A visual inspection was made of the stream or lake, and the physical conditions noted.

The surface water sampling stations have been established at or near stream-gaging stations wherever possible, so that accurate flow data can be obtained for the time of sample collection. Estimates of flow were made by the person doing the sampling at all stations. Where gages were absent, the estimated flows were reported.

#### Laboratory Procedures

Methods of mineral, bacterial, and radiological analyses used by the Department of Water Resources, Southern District, are generally those described in the American Public Health Association, American Water Works Association, and Water Pollution Control Federation publication "Standard Methods for the Examination of Water and Waste Water", 12th edition, 1965. In some cases, the methods described in the following publications also have been used:

U. S. Geological Survey, "Methods for Collection and Analyses of Water Samples", Water Supply Paper 1454, 1960.

U. S. Public Health Service, Taft Sanitary Engineering Center, "Taft Method Analytical Procedure, Alkyl Benzene Sulfonate Determination", 1964.

#### Reporting Methods

Individual chemical constituents of analyses in Table D-2 are reported as parts per million (ppm). Bacteriological analyses are reported as most probable number of coliform bacteria per milliliter (MPN/ml) of sample.

In addition to the chemical constituents reported in Table D-2, oil and grease, phenols, alkalinity, 5-day biochemical oxygen demand (BOD), dissolved oxygen (DO), and free carbon dioxide ( $\text{CO}_2$ ) are reported in parts per million (ppm).

In mid-1965, the soap and detergent industry began its changeover of synthetic detergents (syndets) from alkyl benzene sulfonate (ABS) to linear alkylate sulfonate (LAS), a more readily biodegradable surfactant. Because the standard methylene blue test for surface active agents makes no distinction between ABS and LAS, reported results are given in Table D-2 as methylene blue active substance (MBAS) as ABS in parts per million beginning September 1965. When the existing ABS inventories are exhausted and the changeover by the detergent industries to LAS detergent is completed, the analyses of syndets will be reported as MBAS as LAS, or LAS.

Trace elements analyses are reported in Table D-3 as parts per billion. These analyses were performed by the United States Geological Survey Laboratory in Sacramento, California. Limitations in the precision of measurements by spectrographic analysis frequently require the reporting of results as less than or more than the amounts presented, as indicated in the footnotes accompanying the table.

Radiological analyses for surface water are reported in picocuries per liter (pc/l) in Table D-4. Water samples collected by the Department of Water Resources were analyzed for alpha and beta activity on both suspended and dissolved solids in the Sanitation and Radiation Laboratory, State Department of Public Health, Berkeley, California. Those samples collected by The Metropolitan Water District of Southern California and the Los Angeles Department of Water and Power were analyzed for gross alpha and beta and gross beta, respectively, in their own laboratories.

#### Accuracy

The water samples presented to the chemist contain unknown dissolved substances. Some of these substances may interfere with the

analyses of other constituents dissolved in the water. Standard methods of analysis minimize errors due to interference. Laboratory procedures identify and measure individual constituents in orderly sequence in such a way that any significant interference can be allowed for or eliminated.

Various tests are available to the chemist to assure precision of the results. Foremost among these is the comparison termed "Balance" of the sums of equivalents per million of cations and anions, which are exactly equal in ionic solutions. The analysis is complete only after this test meets the following requirements:

- (1) Analyses of water having sums of anions less than 5.00 milliequivalents per liter shall not have a difference between total anions and total cations over four percent of the mean value.
- (2) Analyses of water having sums of anions from 5.00 milliequivalents per liter to 10.00 milliequivalents per liter shall not have a difference between total anions and total cations of over three percent of the mean value.
- (3) Analyses of water having sums of anions over 10.00 milliequivalents per liter shall not have a difference between total anions and total cations of over two percent of the mean value.

If the analysis does not meet this test, the constituents are rerun to verify the individual results, or until the reason for the discrepancy is ascertained.

Control of laboratory quality of analytical results is maintained by splitting selected authentic water samples, distributing these to the laboratories, and comparing the analytic reports. From time to time synthetic water reference samples, supplied by United States Public Health Service or California Department of Public Health, containing known proportions of selected constituents, are used as tests of precision of an analytical method. These latter serve as a test of laboratory accuracy as well.

Trace elements analyses are reported to be quantitatively accurate to within ten percent of the true value.

Radioactivity counts are measures of statistically random independent events. They are subject to environmental, instrumental, and procedural variations that must be estimated and accounted for to eliminate their influences on the reported results. The results are reported as the count plus or minus the counting error.

Bacteriological counts are made on paired samples of water using the multiple-tube fermentation technique. The accuracy of any single test will depend on the number of tubes used and on the historical bacteriological data of the sampling station.

#### Significant Numbers

Analytical numerical results follow the recommendations for reporting of "Standard Methods". In general, the number of digits retained in chemical analyses reflects the precision of a determination of one-half unit in the last digit. Accuracy (reproducibility) is estimated at plus or minus five percent at critical limits for most constituents.

### Limitations

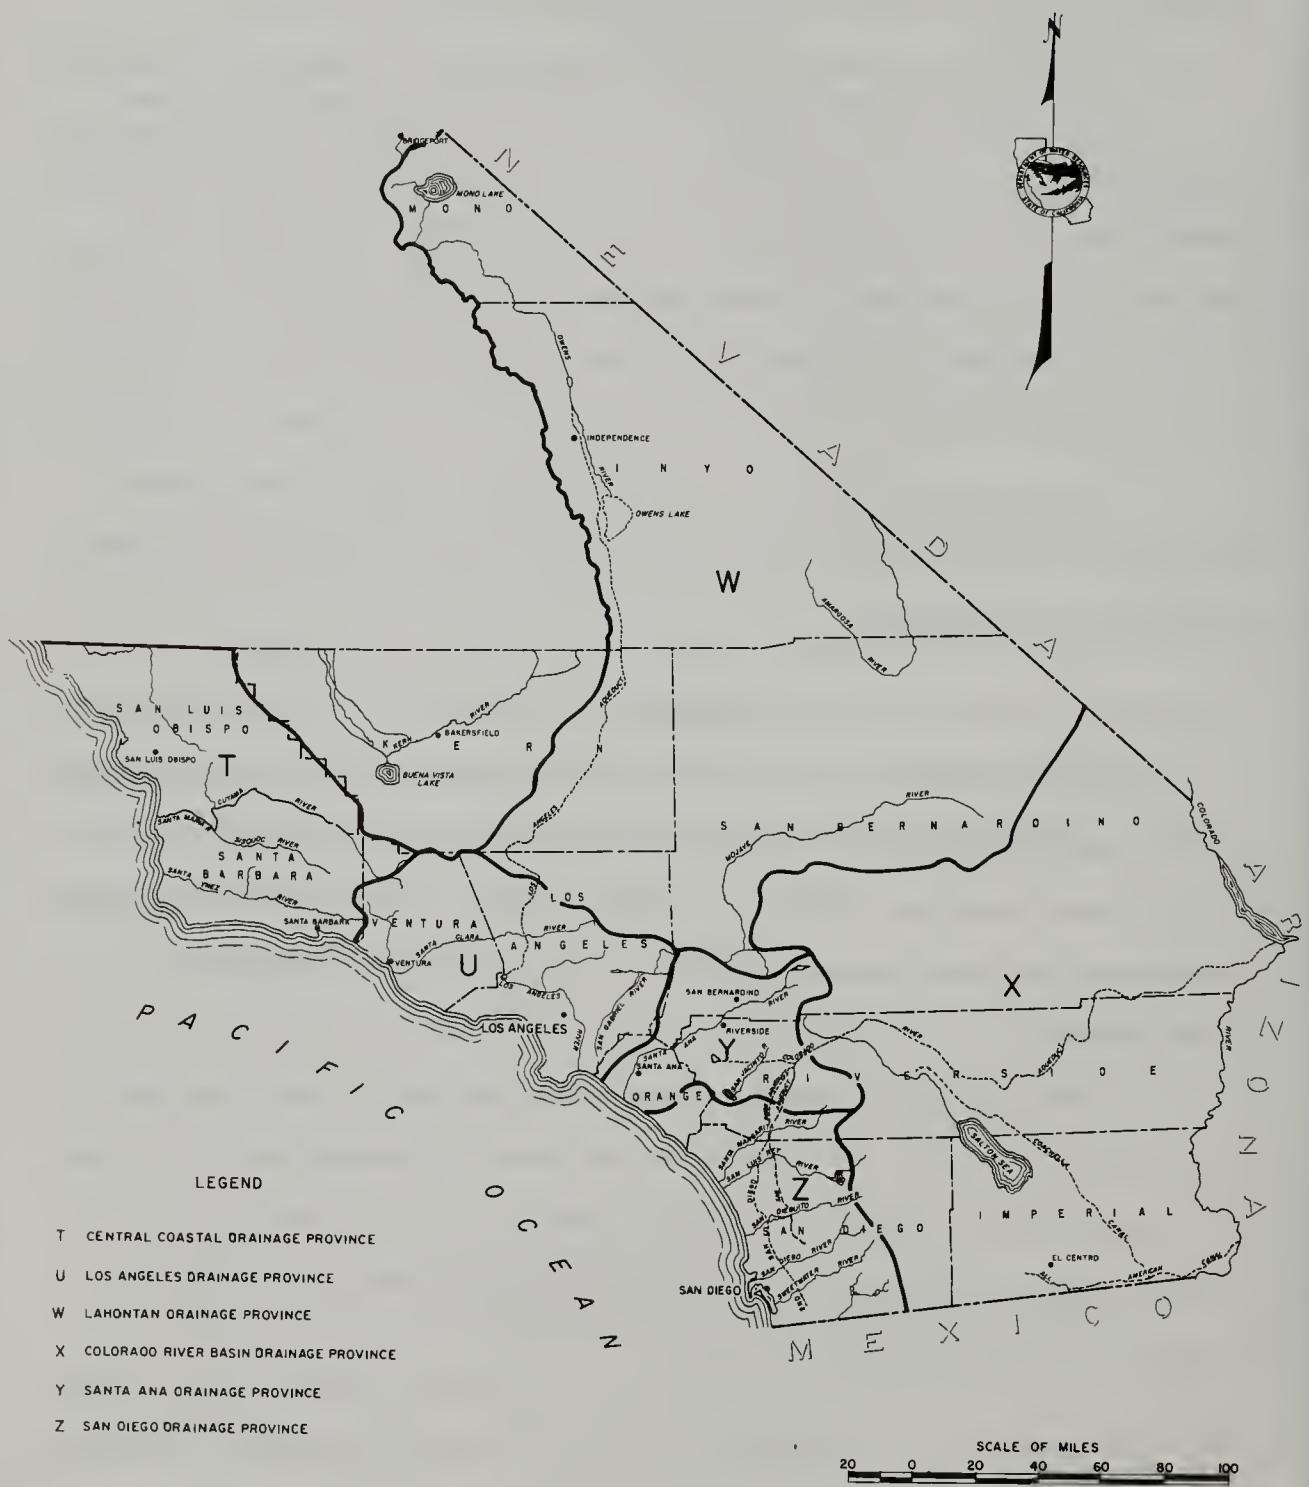

To obtain a representative sampling of the surface waters and of conditions in Southern California, a network of sampling stations was established to cover the streams, lakes, and reservoirs. However, the coverage and the frequency of sampling are limited by physical and economic factors. A compromise is made between the completeness desired in the water quality records and the funds available for the program.

All samples are given a complete mineral analysis and, where indications warrant, special analyses are made such as those for synthetic detergents and phosphates.

### Coding

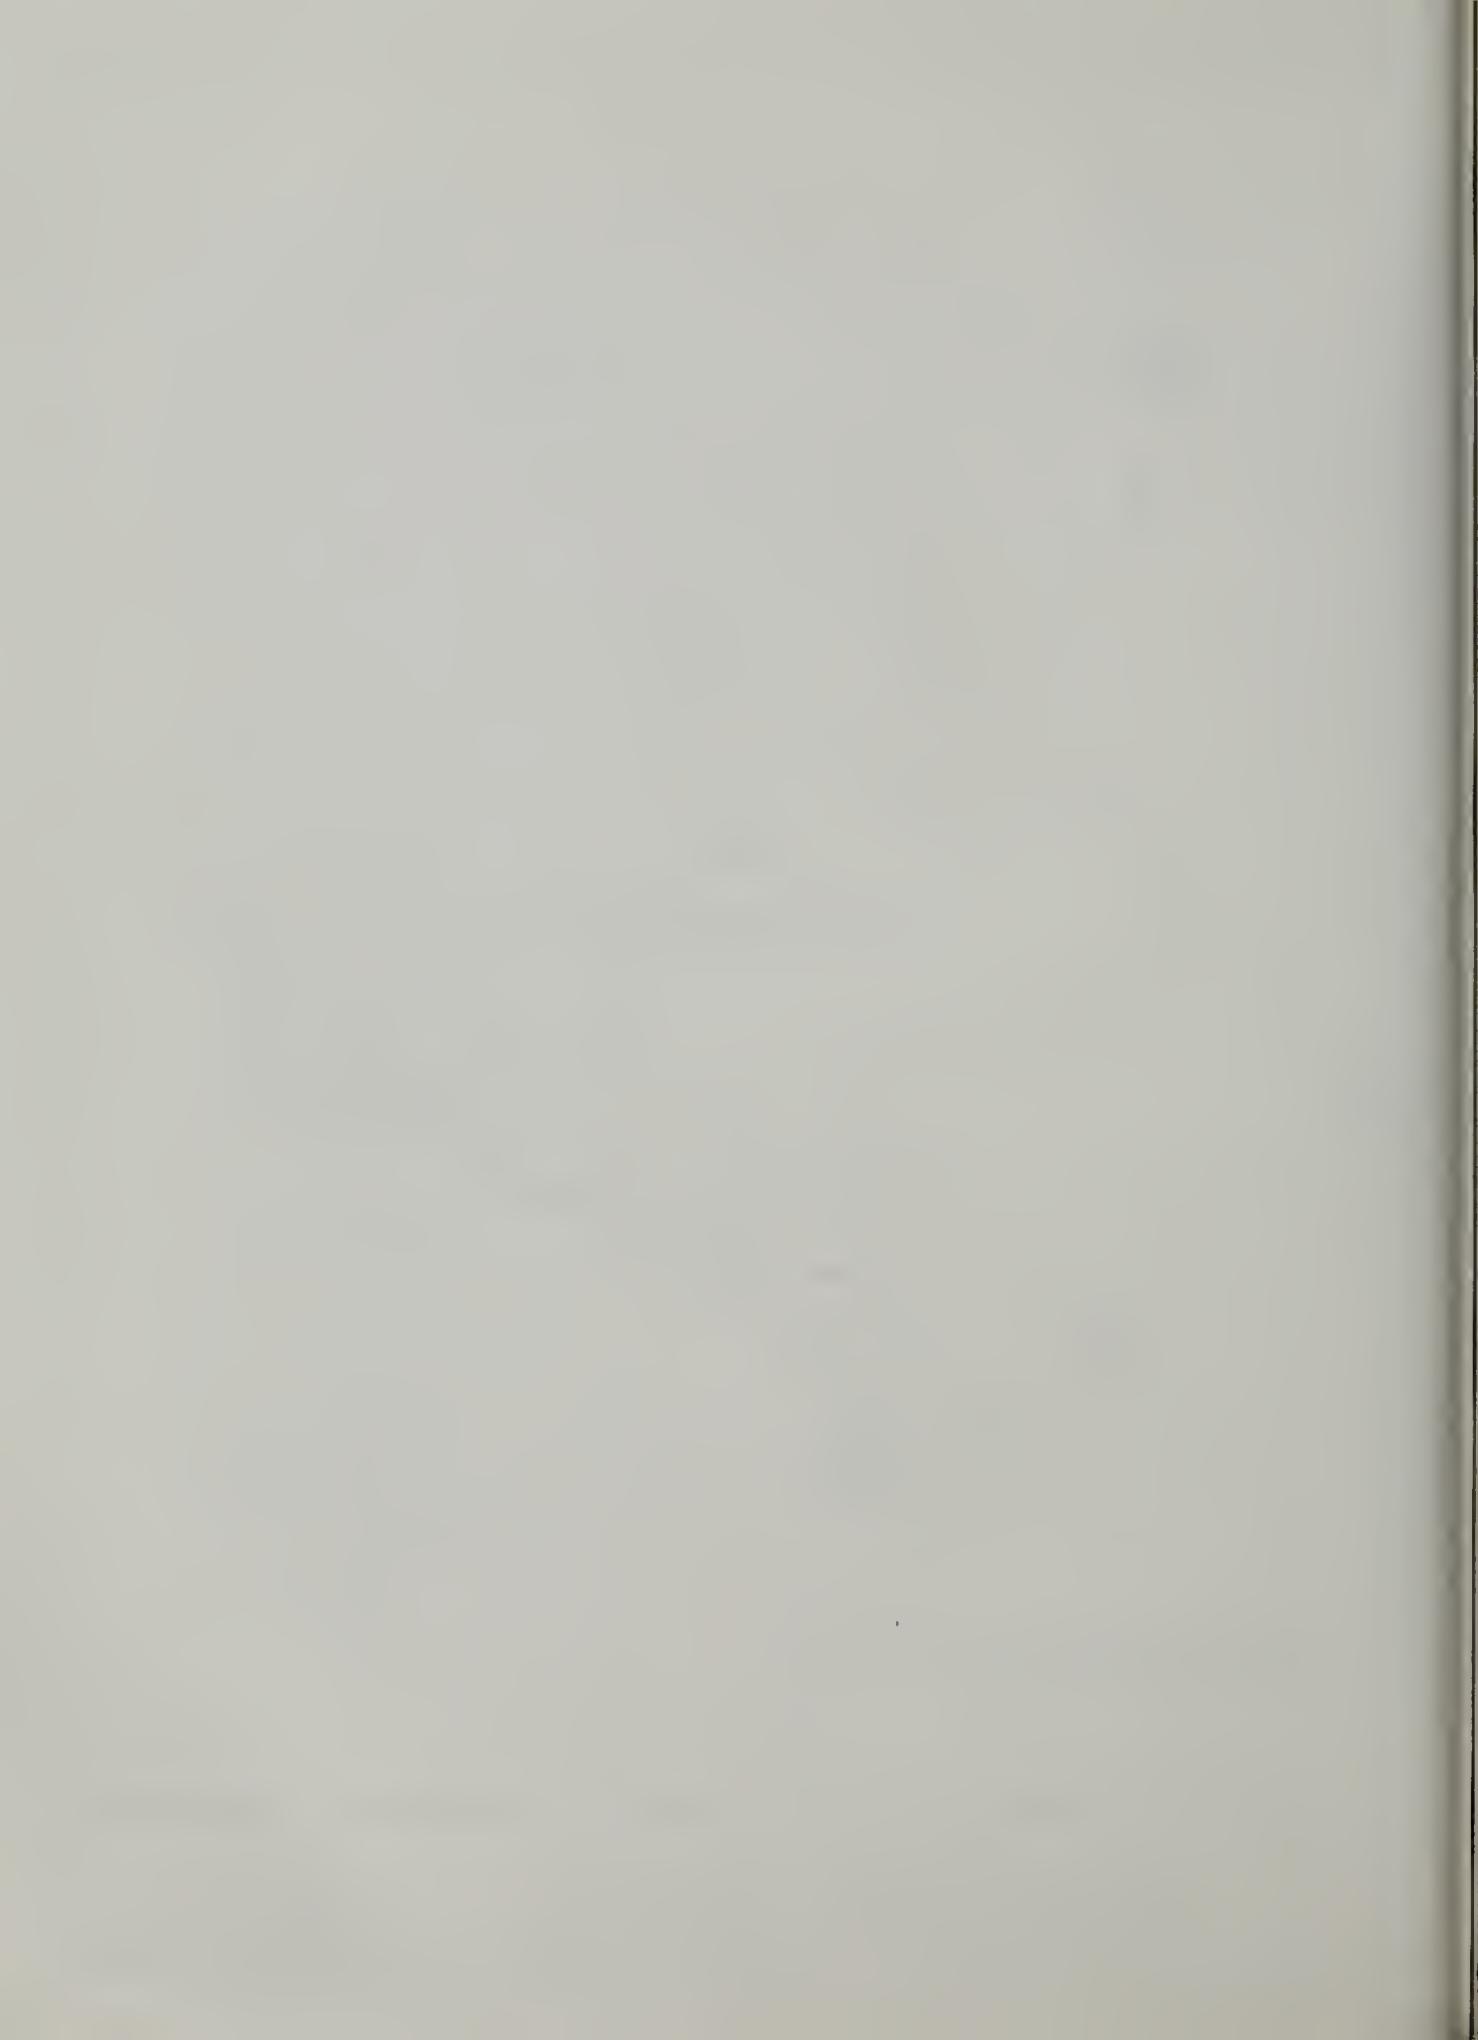

To facilitate the processing of basic hydrological data published in this appendix, numerical and letter codes are used to designate the surface water sampling stations. Figure 2 shows a listing and the location of drainage province boundaries, which are used in the data tables in this appendix.

The sampling stations are indexed according to location, with the name of the stream and a brief description of the sampling point. For ready reference, however, arbitrary numbers have been assigned to these stations. An example of a station number is Station No. 65c, San Diego River at Mission Gorge Road.
